

Planets Beyond Our Solar System

In our Solar System, planets orbit the Sun, but many planets orbit other stars in the universe. These other planets are known as exoplanets or more simply planets. If each star in our galaxy is orbited by just one planet, that's already trillions of exoplanets!

Discovery

Looking back, there was possible evidence of exoplanets from 1917. However, the first were only officially detected in the 1990s. New techniques and technology, like space telescopes, have helped us learn about an incredible variety of planets.

Types

When it comes to planets, there is no such thing as normal. Exoplanets can:

- orbit two stars,
- have the shape of a rugby ball,
- be made of rock, metal and/or gas,
- be hot enough to melt metal,
- rain metal or maybe even diamonds!

Examples

Kepler-90 is so hot it turns molecules apart.

55 Cancri e is totally covered in lava and has sparkling skies.

Gl 581 b glows a cherry colour as it's still hot from being formed.

Trappist-1 is the closest planet ever discovered. It reflects less light than coal.

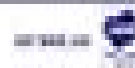

HD 187510 is a smoking blue with lethal weather. It rains glass... sideways!

Fascinating Fact

Exoplanet names usually begin with the telescope that discovered them. Numbers relate to the star that the planet orbits. Lower case letters stand for the order in which the planet was found. The first planet found is always named b, then c, d, and so on.

Most of the exoplanets that have been found are hundreds or even thousands of light years away. One light year is about 9 trillion kilometres (9 trillion miles).
