

BASICS OF C & Ku BAND TRANSMISSIONS & LNBs

A satellite broadcasts a few watts of microwave signals from the geostationary orbit 36,000 kilometers above the earth. The transmissions are also broadcast over a wide "footprint" area. The satellite signals suffer an attenuation of approximately 200 dB, while making this 36,000 kilometer journey from the satellite to reception points on the ground. The satellite signals which finally arrive are extremely weak.

A dish antenna is used to collect these weak satellite signals over a large area - the surface of the dish. These signals are then focussed by the parabolic curvature of the dish, to the focal point. Even at the focal point, the satellite signals are only a few micro-watts.

These tiny satellite signals are received and processed by sophisticated electronic equipment. Given the low signal strength, the signals need to be immediately amplified. However, it is very important that the amplification does not contribute any significant amount of noise which would otherwise spoil the weak signals received. This is done by a "Low Noise Amplifier" - LNA.

The LNA actually consist of 2 or 3 amplifying stages that boost the signal to a reasonable level at which it can be further processed. The LNA is designed with an all out effort to keep noise down to the barest minimum.

NOISE TEMPERATURE

The amount of noise added by the LNA to the received signal is indicated in terms of "Noise Temperature". Noise temperature is specified in degrees Kelvin. For all practical purposes, the lower the noise temperature, the better is the LNA's performance. Approximately 10 years ago, a noise temperature of 24 degrees Kelvin was excellent performance for commercial units. However, with today's improved technology, extremely low noise units such as those from Eurostar, offer a noise temperature of 17 deg. K.

Table 1. Indicates Equivalent Noise Specifications In Degrees Kelvin And dB.
