

The size of the electric current is the rate of flow of electrical charge.

The equation for charge flow is:

$$Q = I \times t$$

Charge flow = Current  $\times$  time

$Q$  = Charge flow (C)

$I$  = Current (A)

$t$  = time (s)

For electrical charge to flow through a closed circuit the circuit must include a source of potential difference. A source of potential difference could be a cell/battery or mains power (from a socket).

Electric current is a flow of electrical charge (electrons).

Current is the same at any point in a series circuit.

Ohm's law links current, potential difference and resistance. The equation for Ohm's law is:

$$V = I \times R$$

Potential difference = Current  $\times$  Resistance

$V$  = Potential difference (V)

$I$  = Current (A)

$R$  = Resistance ( $\Omega$ )

The current ( $I$ ) through a component depends on both the resistance ( $R$ ) of the component and the potential difference ( $V$ ) across the component.

The greater the resistance of the component the smaller the current for a given potential difference (PD) across the component.

The current through an ohmic conductor (at a constant temperature) is directly proportional to the potential difference across the resistor. This means that the resistance remains constant as the current changes.

The resistance of a thermistor decreases as the temperature increases.

A thermistor could be used in a thermostat to detect changes in temperature.

The resistance of an LDR decreases as light intensity increases.

An LDR could be used to switch on lights when it gets dark.

The resistance of components such as lamps, diodes, thermistors and LDRs is not constant. It changes with the current through the component.

The resistance of a filament lamp increases as the temperature of the filament increases.

The current through a diode flows in one direction only. The diode has a very high resistance in the reverse direction.
