Fruit Trees: Training and Pruning Deciduous Trees

There are many ways to train and prune deciduous fruit trees, and no single method is right for all situations and needs. When selecting fruit trees, one important consideration is the desired size of the trees at maturity. Many people prefer small (dwarf and semidwarf) trees because they are easier to manage and harvest and because more trees can be grown in a limited space. Other people prefer full-sized trees because they provide more shade and more fruit per unit area.

GENETIC DWARF TREES

Genetic dwarf trees usually produce very short internodes (the space on a shoot between two leaves), resulting in compact branches with dense foliage. These trees grow to about 8 to 10 feet (2.4 to 3.0 m) tall and wide at maturity. They make beautiful landscape trees that are easily managed to provide adequate amounts of fruit for a single family. Excellent varieties are available in peaches, nectarines, and apples. The lower and interior fruiting branches of genetic dwarf trees, especially peaches and nectarines, tend to die quickly due to shading by the dense growth. However, the trees are small, so production of fruit on the extremities of the higher branches is not a serious problem as long as the branches are strong enough to hold the weight of the fruit.

Pruning genetic dwarf trees mainly involves thinning the branches in the dormant season to open up the canopy and maintain the height and spread of the tree. Control tree size and strengthen limbs by removing branches at their point of attachment to the trunk or a larger branch (thinning cuts), rather than by heading or "topping" them. For definitions of pruning terms, refer to the glossary.

FULL-SIZED AND SEMIDWARF TREES

Full-sized trees on standard rootstocks can grow to 25 to 30 feet (7.6 to 9.1 m) tall, while trees on semidwarfing rootstock can reach 15 to 20 feet (4.6 to 6.1 m) tall. Both standard and semidwarf trees can be kept relatively small by pruning, but trees of this size may still grow too large for many backyard situations. An excellent selection of truly dwarfing apple rootstocks is usually available, and truly dwarfing rootstocks are being developed for most fruit species. Depending on the type of tree (growth habit and location of fruiting buds), full-sized and semidwarf trees may be trained to an open center, central leader, or fruit bush system.

Open Center System

The open center, or vase-shaped, system ([fig. 1](#)) is most commonly used on almond, apricot, cherry, fig, nectarine, peach, plum, and prune trees. Many pear, apple, and pistachio trees are also trained to this system. With this method, the center of the tree is kept free of large branches and vigorous upright shoots (suckers and watersprouts) in order to allow sunlight to reach the lower fruiting wood.

First growing season. To create an open center tree, in about late April of the first growing season select three or four shoots that will become the primary scaffold branches (main structural branches) and pinch back all other strong upright shoots to 4 to 6 inches
