## Introduction

Today, most scientists and engineers are using personal computers with expansion buses for laboratory research, industrial control, and test and measurement. Obtaining proper results from a PC-based D/AQ system depends on each of the system elements (see Figure 1).

- Personal computer
- Transducers
- Signal conditioning
- D/AQ hardware
- Software

## Transducers

Transducers change physical phenomena into electrical signals. For example, thermocouples, RTDs, thermistors, and I/C sensors convert temperature into a voltage or resistance. Other examples include strain gauges, flow transducers, and pressure transducers, which convert force, rate of flow, and pressure to electrical signals. In each case, the electrical signals produced are proportional to the physical parameters they are monitoring.

The thermocouple, for example, combines dissimilar metals to generate voltages that vary with temperature. Thermocouple outputs are very low-level and change only  $7 \mu\text{V}$  to  $40 \mu\text{V}$  for every one degree (C) change in temperature. Accurate temperature measurements therefore require a signal

conditioning system that can amplify the signal with high gain and very little noise and distortion. Thermocouple measurements need cold junction compensation. This compensation corrects for voltages that are formed at the connection of the thermocouple leads to the dissimilar metals. By sensing the reference temperature of the connection points, compensation hardware or software subtracts out this error voltage from the measured thermocouple voltage. Many signal conditioning accessories include an I/C temperature sensor for this purpose.

Other transducers, such as the resistance temperature detectors (RTDs), thermistors, and strain gages, respond to changes in temperature or strain with varying electrical resistance. These resistive sensors require an accurate excitation current or voltage source to sense the change in resistance. Thermistors have a relatively high resistance and can typically be measured with a voltage source and one reference resistor. However, RTDs and strain gages are low resistance, low-sensitivity devices that need additional circuitry to enhance their sensitivity and account for lead wire resistance. RTDs are often used in a 4-wire configuration; one pair of wires carries the excitation current and the other pair senses the RTD voltage. This 4-wire configuration avoids errors due to lead resistance because current does not flow in the leads connected to the measurement

system. The signal conditioning requirements for these and other common transducers are listed in Table 1.

## Signal Conditioning

Transducer outputs must often be conditioned to provide signals suitable for the D/AQ board. Signal conditioning accessories amplify low-level signals, isolate, filter, excite, and bridge complete transducers to produce high level signals for the D/AQ board.

**Amplification** - The most common type of conditioning is amplification. Low-level thermocouple signals, for example, should be amplified to increase the resolution and reduce noise. For the highest possible accuracy, the signal should be amplified so that the maximum voltage range of the conditioned signal equals the maximum input range of the A/D C.

The SCXI front-end signal conditioning system for your D/AQ board has several modules that amplify input signals. The gain is applied to the low-level signals within the SCXI chassis located close to the transducers, sending only high-level signals to the PC, minimizing the effects of noise on the readings.

**Isolation** - Another common application for signal conditioning is to isolate the transducer signals from the computer for safety purposes. The system being monitored
