HOMEOSTASIS

What is photosynthesis and growth?

The two types of response you need to know about should be familiar to you from GCSE:

Phototropism = growth of a plant in response to light

Geotropism = growth of a plant in response to gravity

You also need to know about the role of auxin:

Auxin = indoleacetic acid (an auxin) is a hormone

Important concept to understand: **cell elongation**

In roots, auxin causes cell elongation, which

helps the root to grow in response to light

1. Cells in the tip of the shoot produce auxin
2. Auxin is transported down the shoot (polar transport)
3. Auxin concentration increases at the shoot tip
4. Auxin promotes cell elongation on the shoot
5. The rate of growth of shoot cells is light dependent

Diagram showing how this works:

Diagram of growth in roots

Structure of a multipolar neurone

From what you already know from synapses, there are two neurones. However, you only need to know the structure of one.

Cell body

Information is sent through the nervous system along neurones with the following structure:

- A bundle of neurones = a nerve
- Neurones coordinate activities of organs/structures in the CNS and effector muscles + glands

Diagram of a multipolar neurone:

Cell structures and their functions:

Dendrites = receive all the neural cell information, associated with production of action potential

Soma (cell body) = contains nucleus + cytoplasm + organelles

Axon = carries nerve impulses from other neurones

Diagram of growth in roots

Diagram showing the structure of a synapse

How does a synapse work? It is a junction between two neurones where the electrical signal is converted into a chemical signal. The signal is carried by neurotransmitters. The signal is then converted back into an electrical signal.

Neurotransmitter = a type of chemical messenger that carries the signal across the synapse

Diagram showing the structure of a neuromuscular junction:

Maintaining a gradient of sodium ions in the medulla for the loop of henle

The main function of the loop of henle is to maintain a gradient of sodium ions in the medulla. In order to do this, it must maintain a gradient of sodium ions in the medulla.

How it works and why - key points:

1. The loop of henle acts as a counter current multiplier
 - It maintains the water potential gradient
 - allowing water to leave the collecting duct / DCT by osmosis
2. Na⁺ ions are actively transported out of ascending limb
 - descending limb is impermeable to water so water remains in ascending limb
 - This increases the concentration of Na⁺ in the medulla so lowers the water potential
3. Water moves out of the descending limb / collecting duct by osmosis into the medulla
 - descending limb is permeable to water
 - so water is reabsorbed by capillaries
 - fluid becomes more concentrated as it moves down the 'funnel'
4. Na⁺ diffuses into descending limb
 - This increases Na⁺ in the loop of henle
 - This increases the water potential further
