

MODULE 2. MICROBIAL ANATOMY

What is microbial anatomy and physiology?

- Can reasonably be defined as “structure–function relationships in microorganisms, especially how microbes respond to their environment”, under physiologically relevant conditions.

Bacteria Cell Structure

Figure 1

Anatomical Parts:

- **Capsule** - Some species of bacteria have a third protective covering, a capsule made up of polysaccharides (complex carbohydrates).
 - to keep the bacterium from drying out and to protect it from phagocytosis (engulfing) by larger microorganisms.
 - The capsule is a major virulence factor in the major disease-causing bacteria, such as *Escherichia coli* and *Streptococcus pneumoniae*.
 - Non-encapsulated mutants of these organisms are avirulent, i.e. they don't cause disease.
- **Cell Envelope** - The cell envelope is made up of two to three layers: the interior cytoplasmic membrane, the cell wall, and – in some species of bacteria – an outer capsule.
- **Cell Wall** - Each bacterium is enclosed by a rigid cell wall composed of peptidoglycan, a protein-sugar (polysaccharide) molecule.
 - The wall gives the cell its shape and surrounds the cytoplasmic membrane, protecting it from the environment.
 - It also helps to anchor appendages like the pili and flagella, which originate in the cytoplasmic membrane and protrude through the wall to the outside.
 - The strength of the wall is responsible for keeping the cell from bursting when there are large differences in osmotic pressure between the cytoplasm and the environment.
- **Cell wall composition** varies widely amongst bacteria and is one of the most important factors in bacterial species analysis and differentiation.
 - For example, a relatively thick, meshlike structure that makes it possible to distinguish two basic types of bacteria.
 - A technique devised by Danish physician Hans Christian Gram in 1884, uses a staining and washing technique to differentiate between the two forms. When exposed to a gram stain, gram-positive bacteria retain the purple color of the stain because the structure of their cell walls traps the dye. In gram-negative bacteria, the cell wall is thin and releases the dye readily when washed with an alcohol or acetone solution.
