

Resistance Prediction of Planing Hulls: State of the Art

John M. Almeter¹

There are literally dozens of different ways that the boat designer can predict the resistance of planing hulls. The term planing hull is used generically to describe the majority of hard chine boats being built today. No single prediction method is good for all types of planing hulls. Some methods can be relied on to give good predictions for certain boats and other methods can't be relied upon at all. This paper is meant as a reference for designers in selecting resistance prediction methods for planing hulls. It describes numerous resistance prediction methods and gives their variable ranges and the type of planing hulls they are based on or are intended for. Inherent problems or limitations of the methods are stated. The concept of hull shape, which is often neglected in resistance prediction, and its important role are discussed.

Background

THE VARIABLES commonly used in resistance prediction methods include speed, weight, length, beam, midship deadrise, and longitudinal center of gravity. These variables define the basic dimensions and loading of the hull but they fail to accurately describe the hull shape. Hull shape includes terms or variables such as

- beam taper,
- hull warp, and
- concave, convex, or straight sections.

The hull shape can have a major if not dominant impact on a boat's resistance. These characteristics or variables of hull shape are often difficult to describe mathematically. The lines drawings [1] in Fig. 1 all have the same basic dimensions but show a wide variety in hull shape. Even if all the hull shape variables could be described, the problem of trying to incorporate all of these variables into a resistance model is too difficult. The growth in the complexity of the model far exceeds the growth in number of additional variables. The designer needs to select a resistance prediction method which minimizes the error caused by "omitting" hull shape in the resistance prediction. This is done by selecting a resistance prediction method which best reflects the designer's hull shape. Planing hull series try to keep the hull shape fixed by simply stretching the hull in one direction or the other. Good resistance prediction methods are based on a particular hull type or class (hull shape). The boat designer needs to make sure that the craft not only falls in the dimensional and nondimensional range of a resistance method, but also within the hull shape range.

Inspection of a prediction method's parent hull lines drawing or hull shape description may tell the designer if a method will match his hull. The selection of a prediction method is simplified if the designer can place the design into a class or category. Planing craft often fall neatly into categories or types such as offshore high-speed monohull raceboats. In this example almost all of the boats have very similar hull shapes and their nondimensional variables fall in a small range. The hull shape is for all practicality fixed, and the powering or resistance prediction model can be reduced to a comparatively few variables based on a few random craft of this class.

Fig. 1 Different hull shapes

It is not uncommon for designers of this type of craft to accurately predict resistance or power using simple formulas or graphs based on their experiences. These same models would probably give a poor prediction for other types of craft such as a 20-knot crewboat.

By knowing the type of hull shape a resistance prediction method is based on or is intended for, it becomes much easier to select the appropriate method. Planing hulls with the same basic dimensions intended for the same speed regime often have a very similar hull shape and similar resistance. The following are basic speed regimes which can drive hull shape.

- *Pre-planing:* Up to approximately F_{no} 2.5. This normally covers up to and including hump speed. In pre-planing the bulk of the craft's weight is supported by buoyancy.
- *Semi-planing:* Approximately from F_{no} 2.5 to 4.0. At this speed range the craft's weight is supported by both hydrostatic and dynamic forces. As the speed increases the dynamic forces increase, hydrostatic forces decrease and dynamic trim tends to decrease.
- *Fully planing:* Approximately F_{no} 4.0 and above. At this speed range the craft's weight is almost entirely supported
