

Chapter 17: Nucleic Acids and Protein Synthesis

- **What are the main structural features of nucleosides and nucleotides?**
 - A nucleoside contains a monosaccharide joined to a nitrogen-containing base. A nucleotide contains a monosaccharide joined to a nitrogen-containing base, and a phosphate bonded to the 5'-OH group of the monosaccharide. The monosaccharide is either ribose or 2-deoxyribose, and the bases are abbreviated as A, G, C, T, and U.
- **How do the nucleic acids DNA and RNA differ in structure?**
 - DNA is a polymer of deoxyribonucleotides, where the sugar is 2-deoxyribose, and the bases are A, G, C, and T. DNA is double stranded. RNA is a polymer of ribonucleotides, where the sugar is ribose, and the bases are A, G, C, and U. RNA is single stranded.
- **Describe the basic features of the DNA double helix.**
 - DNA consists of two polynucleotide strands that wind into a right-handed double helix. The sugar-phosphate backbone lies on the outside of the helix and the bases lie on the inside. The double helix is stabilized by hydrogen bonding between complementary base pairs, A pairs with T and C pairs with G.
- **Outline the main steps in the replication of DNA.**
 - An original DNA molecule forms two DNA molecules, each of which has one strand from the parent DNA and one new strand. In replication, DNA unwinds, and the enzyme DNA polymerase catalyzes replication on both strands. The identity of the bases on the template strand determines the order of the bases on the new strand, with A pairing with T and C pairing with G.
- **List the three types of RNA molecules and describe their functions.**
 - Ribosomal RNA (rRNA) provides the site where proteins are assembled. Messenger RNA (mRNA) contains the sequence of nucleotides that determines the amino acid sequence in a protein. Transfer RNA (tRNA) contains an anticodon that identifies the amino acid that carries on its acceptor stem and delivers that amino acid to a growing polypeptide.
- **What is transcription?**
 - Transcription is the synthesis of mRNA from DNA. The DNA helix unwinds, and RNA polymerase catalyzes RNA synthesis from the 3' to 5' end of the template strand, forming mRNA with complementary bases.
- **What are the main features of the genetic code?**
 - mRNAs contain sequences of three bases called codons that code for individual amino acids. There are 61 codons that correspond to the 20 amino acids, as well as three stop codons that signal the end of protein synthesis.
- **How are proteins synthesized by the process of translation?**
 - Translation begins with initiation, the binding of the ribosomal subunits to mRNA and the arrival of the first tRNA with an amino acid. During elongation, tRNAs bring individual amino acids to the ribosome one after another, and new peptide bonds are formed. Termination occurs when a stop codon is reached.
- **What is a mutation and how are mutations related to genetic diseases?**
 - Mutations are changes in the nucleotide sequence in a DNA molecule. A point mutation results in the substitution of one nucleotide for another. Deletion and insertion mutations result in the loss or addition of nucleotides, respectively. A mutation that causes an inherited condition may result in a genetic disease.
- **What are the principal features of DNA fingerprinting?**
 - DNA fingerprinting is used to identify an individual by cutting DNA with enzymes to give a unique set of fragments.
