

## Full Vehicle NVH Analysis with Rolling Tires

### Summary

In a traditional automobile noise, vibration and harshness (NVH) analysis, stationary tires are defined and subjected to vertical dynamic loading. The actual operating conditions of a tire involve rolling however, and the vibration characteristics of rolling tires are considerably different from those of stationary tires.

Abaqus offers a methodology to include the pre-loading and gyroscopic effects of rolling tires in a forced response dynamic analysis of the moving vehicle. This article closely follows SIMULIA Technology Brief TB-08-TVC-1 and illustrates the use of substructures in a typical NVH analysis for a full vehicle model with steadily rolling tires.

### Background

Small amplitude vibrations of a tire on the road can be treated as a linear superposition of small amplitude steady state vibrations on a highly nonlinear base state. For stationary tires, this base state is the footprint configuration of the tire. The base state contains nonlinearities arising from the load-deflection behavior of various rubber compounds, contact between the tire and the road, reinforcement behavior, etc.

In a traditional NVH analysis, the tires are stationary and subjected to vertical load. However, the vibration characteristics of rolling tires depend on the rolling velocity and are considerably different from those of stationary tires. Specifically, the rolling condition contributes loads in the fore-aft direction as well as the vertical [Ref 1].

It is common practice to employ a mixed Eulerian-Lagrangian scheme to compute the steady state rolling configuration of the tire. This methodology uses a reference frame that is attached to the axle of the rotating tire. An observer in this frame sees the tire as points that do not move, although the material of which the tire is made moves through these points. Small amplitude vibrations can then be superposed on the rolling configuration corresponding to the velocity of interest.

The dynamic substructure of a rolling tire can be created and incorporated in a full vehicle assembly, thus eliminating the need to use a fully meshed representation of the tire. With these modeling capabilities, tire manufacturers can provide automotive designers with richer, more comprehensive numeric representations of their tire's behavior – without divulging their detailed tire FE models.

### Key Abaqus Features and Benefits

- Symmetric model generation and symmetric results transfer
- A mixed Eulerian-Lagrangian scheme to compute the steady state rolling configuration of tires
- Dynamic substructures to account for pre-loading and gyroscopic effects of a rolling tire
- Subspace-based steady state dynamics for relatively inexpensive forced response prediction

The simulation presented here demonstrates the analysis methodology for including the effect of rolling tires on the vehicle forced frequency response. A dynamic substructure of a rolling tire FE model is created and assembled into a full vehicle model for NVH analysis. The automatic multi-level substructuring (AMS) eigensolver is used to extract the eigensolution of the vehicle assembly, which is then subsequently used in the steady-state dynamic analyses.

### Finite Element Analysis Approach

The model under consideration represents a typical passenger car tire. The road is modeled as an analytical rigid surface. Contact is defined between this surface and the tire. A simple Mooney-Rivlin law is used for the strain energy potential of the various rubber materials. This simulation ignores the viscoelastic nature of the rubber. The plies and belts are modeled using rebar layers embedded in the surrounding rubber matrix. Linear elastic material properties are applied to the reinforcement fibers.
