Parametric Finite-Volume Micromechanics of Uniaxial Continuously-Reinforced Periodic Materials With Elastic Phases

The finite-volume direct averaging micromechanics (FVDAM) theory for periodic heterogeneous materials is extended by incorporating parametric mapping into the theory's analytical framework. The parametric mapping enables modeling of heterogeneous microstructures using quadrilateral subvolume discretization, in contrast with the standard version based on rectangular subdomains. Thus arbitrarily shaped inclusions or porosity can be efficiently rendered without the artificially induced stress concentrations at fiber/matrix interfaces caused by staircase approximations of curved boundaries. Relatively coarse unit cell discretizations yield effective moduli with comparable accuracy of the finite-element method. The local stress fields require greater, but not exceedingly fine, unit cell refinement to generate results comparable with exact elasticity solutions. The FVDAM theory's parametric formulation produces a paradigm shift in the continuing evolution of this approach, enabling high-resolution simulation of local fields with much greater efficiency and confidence than the standard theory. 1 Introduction

A major objective of micromechanics is to predict average (also called effective or homogenized) elastic moduli from a knowledge of the elastic moduli, shapes and distribution of the individual phases that make up the heterogeneous material. Just as important is the ability to accurately predict the local stress and strain fields that may produce local inelastic behavior, damage, and ultimately failure. Such capability, if sufficiently accurate, can be used at both the structural and material design and optimization levels. Specifically, it can be used to efficiently identify the proper combination of materials for the desired overall properties, thus reducing considerably the large expense associated with the traditional trial-and-error approach based on the actual fabrication and laboratory testing.

Two distinct micromechanical modeling approaches based on two types of material microstructure representation can be identified, Drago and Pindera [1]. One representation is based on material microstructures with statistically homogeneous distribution of phases for which a representative volume element (RVE) with the same statistical information representative of the material at large can be identified at each continuum point. Its average properties are determined by solving the RVE boundary-value problem under homogeneous displacement or traction boundary conditions, which produce homogeneous stresses and deformations in the equivalent or homogenized material. The second representation is based on microstructures that are periodic, Fig. 1. Periodic materials are composed of building blocks called repeating unit cells (RUCs) that admit arbitrary internal microstructures. Since one RUC is indistinguishable from another, the response of the entire array under macroscopically uniform loading is identical to

the response of an arbitrary RUC under the same loading. This loading is specified by periodic boundary conditions that involve both surface displacements and tractions.

Methods for the analysis of periodic materials have become dominant in the past 20 years due to the difficulty of simultaneously satisfying homogeneous displacement and traction boundary conditions, necessary in fulfilling the RVE requirement, for subvolumes with arbitrary microstructures. In particular, the homogenization theory has emerged as a powerful technique in the analysis of periodic materials. This technique employs a multiscale displacement representation in the solution of the RUC problem, which leads to the determination of the effective or homogenized elastic moduli and the internal strain and stress fields, see Sanchez-Palencia [2] and Suquet [3]. The solution of the RUC boundary-value problem, however, is typically generated using the finite-element method.

An attractive alternative to the finite-element approach in the solution of periodic RUC problems is the finite-volume theory developed by Bansal and Pindera [4,5]. As recently demonstrated by Pindera and Bansal [6], many microstructural features and response characteristics of real unidirectional composites are efficiently simulated by this method. The method's development is rooted in the so-called higher-order theory for functionally graded materials originally developed by Aboudi, Pindera, and Arnold in a sequence of papers published in the 1990s and summarized in a review article by Aboudi et al. [7]. Incorporation of periodic boundary conditions into this higher-order theory within the homogenization framework has produced a micromechanics model for periodic materials called high-fidelity generalized method of cells (HFGMC), Aboudi et al. [8,9]. Subsequent reconstruction of this micromechanics model based on a substantially simplified RUC volume discretization, and the use of the local/global stiffness matrix approach, see Butler [10] and Pindera [11], has demonstrated this theory to be a finite-volume, direct-averaging, micromechanics (FVDAM) model. This reconstruction was motivated by a similar reconstruction of the original higher-order theory for functionally graded materials by Zhong et al. [12] and

Homogenization of Coupled Phenomena in Heterogenous Media Jean-Louis Auriault, Claude Boutin, Christian Geindreau, 2010-01-05 Both naturally occurring and man made materials are often heterogeneous materials formed of various constituents with different properties and behaviours Studies are usually carried out on volumes of materials that contain a large number of heterogeneities Describing these media by using appropriate mathematical models to describe each constituent turns out to

be an intractable problem. Instead they are generally investigated by using an equivalent macroscopic description relative to the microscopic heterogeneity scale which describes the overall behaviour of the media. Fundamental questions then arise: Is such an equivalent macroscopic description possible? What is the domain of validity of this macroscopic description? The homogenization technique provides complete and rigorous answers to these questions. This book aims to summarize the homogenization technique and its contribution to engineering sciences. Researchers, graduate students and engineers will find here a unified and concise presentation. The book is divided into four parts whose main topics are: Introduction to the homogenization technique for periodic or random media with emphasis on the physics involved in the mathematical process and the applications to real materials; Heat and mass transfers in porous media; Newtonian fluid flow in rigid porous media under different regimes; Quasi statics and dynamics of saturated deformable porous media. Each part is illustrated by numerical or analytical applications as well as comparison with the self consistent approach.

Micromechanics of Heterogeneous Materials Under Compressive Loading George Laird, 1993

In mining and mineral processing compressive loading is often encountered during the comminution of ore bearing minerals and in the wear resistant materials used in the comminution circuit. A common thread joining many of the materials that are primarily used under compressive loading is the presence of a high modulus reinforcement either fiber or particulate embedded within a lower modulus matrix phase i.e. a brittle heterogeneous material. Many of these heterogeneous materials are designed or manufactured such that an imperfect interface i.e. an interface that provides less than complete coherency between the reinforcing phase and the matrix exists between the reinforcing phase and the matrix e.g. tough fiber reinforced ceramics. To date most research has focused on the response of these heterogeneous materials with imperfect interfaces to tensile loading however little is known about their response to compressive loading. The principal objective of this investigation is to develop a better understanding of the micromechanical behavior of these complex materials under compressive loading. Analytical solutions are reviewed and compared with finite element models for the simulation of heterogeneous materials with imperfect interfaces under compressive loading. This comparison shows that a nonlinear numerical approach finite element method is necessary to fully simulate the behavior of these materials. To validate the nonlinear model laser moiré experiments were conducted on a model heterogeneous material loaded under uniaxial and biaxial compression. In plane displacements were measured and found to be in fundamental agreement with the nonlinear finite element model. Subsequently finite element simulations were developed for a variety of heterogeneous materials with imperfect interfaces. Results show that deleterious tensile stress concentrations are primarily influenced by three factors: i) the nature of the imperfect interface; ii) the moduli mismatch between the reinforcement and matrix; and iii) the volume fraction of the reinforcement. Finally crack initiation experiments in laboratory models of a heterogeneous material with a frictional imperfect interface were conducted to substantiate the prior work using nonlinear finite element models. Experimental results correlate well with the numerically predicted

performance of Self OPTIM has been proven by both numerical and experimental verifications. Second, in the stochastic finite element method SFEM, the spatially varying random material properties such as linear elastic modulus, Poisson's ratio, and initial yield strength are discretized by the Karhunen-Loève expansion. This computational tool allows for Monte Carlo simulations considering material uncertainties and their propagations through forward simulations. By combining SFEM with Self OPTIM, a novel algorithm named as stochastic Self OPTIM for stochastic material characterization of heterogeneous media with randomly distributed material properties is invented. Its performance has been verified by applying to reconstruction problems and stochastic inverse identifications of statistical parameters of random fields related to material properties. To demonstrate promising applications of the stochastic Self OPTIM, a probabilistic low cycle fatigue life prediction model has been developed with considerations of spatial variability of Young's modulus, Poisson ratio, and the initial yield strength. For this purpose, a probabilistic surrogate model has also been developed by using the polynomial chaos expansion.
