**Dynamics of Distributed Feedback Lasers and Semiconductor Laser Arrays** Yuan-Hwang Liao, 1997 Low threshold organic thin-film laser devices Christian Karnutsch, 2007-07-25 In this work low threshold organic semiconductor lasers emitting throughout the entire visible wavelength range are presented Organic semiconductor lasers OSLs are a fascinating class of laser devices that have a huge potential for sensing and display applications Their ease of fabrication and tuneability across the full visible wavelength range are only a few of their advantageous properties which fueled intense research towards organic laser devices For future electrically pumped organic lasers as well as for compact laser diode pumped devices reduction of the organic laser threshold is of crucial importance since low optically pumped thresholds translate into lower current densities required for injection lasing With blue emitting one dimensional first and second order distributed feedback DFB lasers based on the copolymer BN PFO laser operation in a wavelength range from 438 to 459 nm was realized For an optimized second order laser we obtained a very low threshold energy of 280 pJ pulse which could be further reduced to 160 pJ pulse by employing first order feedback These very low threshold values render BN PFO a very promising material for future organic semiconductor laser diodes Furthermore we have investigated DFB lasers based on a mixed order resonator concept and the polyfluorene derivative F8DP We showed that this improved resonator concept is a very promising design which combines the advantages of first and second order DFB resonators By varying the grating parameters organic solid state lasers with customized properties can be fabricated Optimizing the polymer film parameters led to a very low laser threshold of 45 pJ pulse 36 nJ cm<sup>2</sup> which is among the lowest values ever reported for organic semiconductor lasers These DFB lasers have been optically pumped by frequency tripled Nd YVO<sub>4</sub> lasers or complex optical parametric oscillator OPO systems resulting in versatile but expensive and bulky laser sources For many applications e g for laser based analytical techniques and sensors much more compact and inexpensive all solid state laser sources are desirable Whilst an organic injection laser doesn't exist it might prove useful for numerous applications to adopt an indirect electrical pumping scheme using efficient and compact electrically driven light sources to pump an OSL optically The recent evolution of blue violet emitting inorganic In GaN laser diodes renders them attractive as such a pump source During the course of this work a very compact all solid state laser system using a low cost pulsed In GaN laser diode has been realized Laser emission spanning the complete visible wavelength range was achieved by employing a variety of organic materials and resonator geometries As a future asset these hybrid organic inorganic lasers could be made mechanically tuneable by either using a wedge shaped organic thin film or by spatially varying the lattice period Both concepts alter the emission wavelength when the organic laser is moved mechanically in front of the focussed pump laser diode These hybrid laser systems could provide the basis for innovative portable analysis systems e g for medical point of care sensor systems An even lower cost pumping

scheme based on LEDs could lead to extremely low cost and versatile laser sources emitting throughout the entire visible wavelength range. But the ultimate goal remains the realization of an electrically pumped organic laser diode. In the course of this thesis a self-consistent numerical simulation tool was employed to carry out comprehensive investigations of the influence of various parameters on the laser threshold in electrically pumped multilayer OSLs. It could be shown that the threshold current densities necessary for lasing in an organic laser diode structure will be of the order of 500–1000 A/cm<sup>2</sup>. The main reasons for these high threshold values are waveguide losses, excited state absorptions, bimolecular annihilation processes. In order to reduce the waveguide losses, two concepts have been discussed: either using thin active layers in combination with low-loss transparent conductive oxide (TCO) electrode materials or using thick doped multilayer devices with metal electrodes. The threshold current density is also negatively influenced by polaron and excited state absorption. The dimensionless quantity has been introduced to quantify the effect of polaron and excited state absorption in the device. It saturates at increasing current densities, implying that polaron and triplet-triplet absorption might prevent electrically pumped devices from lasing for all current densities depending on the respective absorption cross sections. It was shown that this does not strongly depend on the device geometry. For the studied devices, an increased charge carrier mobility in the transport layers does not reduce polaron absorption significantly, but if the mobilities in the emission layer and in the transport layers could be increased simultaneously, the effect of polaron absorption would be reduced. We also investigated the influence of bimolecular annihilation processes on the threshold current density using numerical simulations. For a set of typical annihilation and material parameters, the threshold current density was calculated to be 560 A/cm<sup>2</sup>. It was found to depend critically on the emission layer thickness. Singlet polaron and singlet-triplet annihilations were identified as the dominating quenching processes for the investigated parameter range. According to the presented numerical simulations, organic laser diodes will require very high current densities; hence, the current durability of organic materials will be an important issue. Dielectric discharges and thermal breakdown were identified as the major causes for catastrophic device failure under high excitation conditions. Thus, thermal management was identified as a key element to improve device stability. To reduce the thermal load of the devices, high thermal conductivity substrates or pulsed operation can be employed. We were able to demonstrate that organic materials can indeed sustain the required current densities. In high current excitation experiments, more than 550 A/cm<sup>2</sup> could be passed through a thick photocrosslinked hole transport layer in pulsed mode. This very encouraging and significant result shows that photocrosslinked all-polymer devices might be the proper choice to realize an organic injection laser. Apart from the concepts elucidated above, further approaches to an organic injection laser exist. Recently, ambipolar light-emitting organic field-effect transistor (OFET) geometries were discussed in the context of OSLs. But to date, the achieved current densities are typically about one order of magnitude too low. Another promising novel approach is to induce capacitively coupled lasing action in OSLs. An organic active material is sandwiched between two dielectric clad

electrodes and excited via an AC voltage This is advantageous as it avoids the optical losses associated with injecting electrodes close to the active layer This concept will be evaluated in the near future in our group at the LTI

for advanced undergraduate and graduate courses in photonics and an indispensable tool for researchers working in this rapidly growing field *Energy Research Abstracts*, 1979 *Theorie und Simulation des Doppelstreifen-Lasers* Miguel Ángel Palacios Lázaro, 2011-01-13 In der heutigen Welt ist der Informationsaustausch einer der stärksten Motoren der Wirtschaft und der Entwicklung der Gesellschaft. Dementsprechend spielt die Kommunikationstechnik eine immer wichtigere und bedeutendere Rolle im Bereich der Forschung der Technik und der Ausbildung. Neue Systeme werden entwickelt, die existierenden werden ständig verbessert und ihre Datenübertragungsgeschwindigkeit überschreitet weitere Grenzen. Diese Prozesse sind die Antwort auf den wachsenden Bedarf an technischen Lösungen, die das Wachstum der oben genannten wirtschaftlichen und technologischen Welt unterstützen. Unter diesen Lösungen sind optische Übertragungssysteme diejenigen, die höchsten Geschwindigkeiten zur Datenübertragung ermöglichen. Auf sehr langen Strecken können optische Fasern analoge sowie digitale Information übertragen. Der Einsatz von optischen Verstärkern EDFA hat den Umfang dieses Informationsaustausches auf bisher unbekannte Größen gebracht. Als Quelle dieser Systeme werden Laserdioden verwendet, die mit den unterschiedlichsten Technologien entworfen und aufgebaut werden können. Diese Dioden Fabry-Pérot und DFB Laserdiode Heteroübergang Heteroübergang und Quantenbrunnenlaserdiode werden meist mit modulierten Strömen angeregt, sodass die Information im Basisband übertragen wird. Der Einsatz dieser Quellen zur Erzeugung von Mikrowellen- und Millimeterwellenoszillationen ist jedoch ein weniger bekanntes Anwendungsgebiet. Doppelstreifen-Laser sind Halbleiterstrukturen, in denen nicht nur eine aktive Schicht, sondern zwei parallele aktive Streifen vergraben sind. Die Existenz dieser zwei aktiven Bereiche ermöglicht das Entstehen einer Schwingung des vom Halbleiter abgestrahlten Lichts. Dieses Licht kann unter bestimmten Bedingungen moduliert oder als Mikrowellen- bzw. Millimeterwellenoszillator benutzt werden. Diese Arbeit befasst sich mit dieser Art von Strukturen. Die Einleitung der Arbeit stellt die Prinzipien der Erzeugung kohärenten Lichts vor sowie die meist verbreiteten Arten von Laserdioden. Darauf folgend werden die theoretischen Grundlagen der Arbeit präsentiert. Das Ziel unserer Forschung ist die Entwicklung einer Modellierung, die zum theoretischen Begreifen des Doppelstreifen-Lasers beiträgt. Dieses Verständnis soll zur Optimierung dieser Struktur führen. Die Erzeugung einer rauscharmen Oszillation im Bereich von Gigahertz ist der endgültige Zweck der Optimierung. Diese Arbeit geht von der Anwendung eines Wanderwellenmodells aus. Herkömmliche Modellierungen wurden jedoch auf die Simulation von gewöhnlichen Lasern mit einem einzigen aktiven Streifen angewendet. Auf der Theorie dieser Modelle basierend wurde ein Wanderwellenmodell für Doppelstreifen-Laser entwickelt. Das Entstehen von zwei gleichzeitig existierenden lateralen Moden als symmetrische bzw. antisymmetrische Mode bezeichnet die leicht unterschiedlichen Brechungsindizes aufweisen, ermöglicht die Erzeugung der angestrebten Oszillation. Unseren Überlegungen zu Folge sind zwei nachrichtentechnische Anwendungen dieses Phänomens von Bedeutung. Ein Laser kann nur im Basisband moduliert werden. Wird eine vom Bauteil abhängende Frequenz erreicht, fällt die Leistung des Lichts stark ab. Die Bandbreite der modulierenden Signale kann aus diesem Grund

nur einige Gigahertz betragen Die Erzeugung einer Oszillation im Bereich von Gigahertz ermöglicht jedoch die Modulation des Lasers um diese Schwingung was eine zusätzliche Bandbreite zur Signalübertragung bietet wie diese Arbeit bewiesen hat Eine besonders wichtige Anwendung eines Doppelstreifen Lasers kann durch die Optimierung der erzeugten Oszillation erreicht werden Dies führt zu einer rauscharmen Schwingung die eine sehr niedrige Linienbreite aufweist Solche Oszillationen können als Mikro und Millimeterwellenquellen zum Einsatz kommen die über lange Strecken mittels Glasfaser übertragen und verteilt werden was aus nachrichtentechnischer Sicht sehr attraktiv ist Solche engen Linienbreiten können bisher nur mittels komplizierter Systeme z.B. über optische Injektion erreicht werden Die vorliegende Arbeit hat gezeigt dass die dem Doppelstreifen Laser inhärente optische Kopplung eine technisch machbare Reduktion der Linienbreite ermöglicht Die Erweiterung des Wanderwellenmodells und die theoretische Erklärung der zweiten der oben genannten Anwendungen bilden die wichtigsten Ergebnisse der vorliegenden Arbeit die zu einer zukünftigen praktischen Entwicklung solcher Quellen als Grundlage dienen könnten
