Polysaccharides are long polymeric chains of carbohydrates They are composed of monosaccharide units which are linked together by glycosidic linkages These biomolecules react with water to form constituent sugars Marine polysaccharides are carbohydrates of marine origin These are sulfated polysaccharides which are produced by concomitant fixation of sulphur and carbon Some common examples of marine polysaccharides are chitosan chitin carrageenan fucoidan and alginate These carbohydrates are gaining popularity as they have low extraction cost and are soluble in aqueous solution and extraction media Seaweeds and exoskeletons of crustaceans are some of the major resources of marine polysaccharides They find extensive application in the field of pharmaceuticals nutraceuticals cosmeceuticals and tissue engineering There has been rapid progress in this field and its applications are finding their way across multiple industries The various advancements in the study of marine polysaccharides are glanced at and their applications as well as ramifications are looked at in detail The topics covered in this book offer the readers new insights on marine polysaccharides *Marine Polysaccharides Volume 1* Paola Laurienzo (Ed.),2018

Foods and Nutraceuticals Herminia Dominguez, 2013-09-30 Algae have a long history of use as foods and for the production of food ingredients. There is also increasing interest in their exploitation as sources of bioactive compounds for use in functional foods and nutraceuticals. Functional ingredients from algae for foods and nutraceuticals reviews key topics in these areas encompassing both macroalgae seaweeds and microalgae. Proteogenomics of Marine Polysaccharide Utilisation Ben Francis, 2020 Polysaccharide is a major constituent of the total organic carbon that is generated by photosynthetic eukaryotes. In the marine realm, where approximately half of annual global carbon fixation occurs, algae can produce large amounts of polysaccharide during bloom events. Phytoplankton blooms are frequently seasonal phenomena and spring blooms in particular have been a focus of study as they are predictable in space and time. This makes them much more amenable model systems in which to explore the processes that occur as organic carbon is recycled. It is assumed that the bulk of the polysaccharides algae produce serve one of two primary functions, namely acting as an energy storage molecule or they serve as structural polymers in the cell walls. Other polysaccharides may also have protective functions as exudates. Regardless of function in algae, the polysaccharides are a valuable energy source for heterotrophic bacteria. The combination of abundance and predictable or semi-predictable structure of the polysaccharides has led to proliferation of variations on a particular sequestration and degradation strategy among the Bacteroidetes and Gammaproteobacteria that is frequently characterised as being selfish. The strategy is based on uptake of poly- and especially oligosaccharides into the periplasm via the use of TonB dependent transporters. Once in the periplasmic

space oligomers can be further degraded to monomers that can then be transported into the cytosol This
