The Regularized Fast Hartley Transform Keith Jones, 2010-03-10 Most real world spectrum analysis problems involve the computation of the real data discrete Fourier transform DFT a unitary transform that maps elements N of the linear space of real valued N tuples R to elements of its complex valued N counterpart C and when carried out in hardware it is conventionally achieved via a real from complex strategy using a complex data version of the fast Fourier transform FFT the generic name given to the class of fast algorithms used for the efficient computation of the DFT Such algorithms are typically derived by exploiting the property of symmetry whether it exists just in the transform kernel or in certain circumstances in the input data and or output data as well In order to make effective use of a complex data FFT however via the chosen real from complex N strategy the input data to the DFT must first be converted from elements of R to N elements of C The reason for choosing the computational

domain of real data problems such as this to be C rather than R is due in part to the fact that computing equipment manufacturers have invested so heavily in producing digital signal processing DSP devices built around the design of the complex data fast multiplier and accumulator MAC an arithmetic unit ideally suited to the implementation of the complex data radix 2 butterfly the computational unit used by the familiar class of recursive radix 2 FFT algorithms
