FRANK J. VERTUCCI

The hard tissue repository of the human dental pulp takes on numerous configurations and shapes. A thorough knowledge of tooth morphology, careful interpretation of angled radiographs, proper access preparation and a detailed exploration of the interior of the tooth are essential prerequisites for a successful treatment outcome. Magnification and illumination are aids that must be utilized to achieve this goal. This article describes and illustrates tooth morphology and discusses its relationship to endodontic procedures. A thorough understanding of the complexity of the root canal system is essential for understanding the principles and problems of shaping and cleaning, for determining the apical limits and dimensions of canal preparations, and for performing successful microsurgical procedures.

It is important to visualize and to have knowledge of internal anatomy relationships before undertaking endodontic therapy. Careful evaluation of two or more periapical radiographs is mandatory. These angled radiographs provide much needed information about root canal morphology. Martinez-Lozano et al. (1) examined the effect of x-ray tube inclination on accurately determining the root canal system present in premolar teeth. They found that by varying the horizontal angle 20° and 40° the number of root canals observed in maxillary first and second and mandibular first premolars coincided with the actual number of canals present. In the case of mandibular second premolars only the 40° horizontal angle identified the correct morphology. The critical importance of carefully evaluating each radiograph taken prior to and during endodontic therapy was stressed by Friedman et al. (2). In a case report of five canals in a mandibular first molar, these authors emphasized that it was the radiographic appearance which facilitated recognition of the complex canal morphology. They cautioned 'that any attempt to develop techniques that require fewer radiographs runs the risk of missing information which may be significant for the success of therapy'.

Radiographs, however, may not always determine the correct morphology particularly when only a buccolingual view is taken. Nattress et al. (3) radiographed 790 extracted mandibular incisors and premolars in order to assess the incidence of canal bifurcation in a root. Using the 'fast break' guideline (Fig. 1) that disappearance or narrowing of a canal infers that it divides resulted in failure to diagnose one-third of these divisions from a single radiographic view. The evaluation of the root canal system is most accurate when the dentist uses the information from multiple radiographic views together with a thorough clinical exploration of the interior and exterior of the tooth.

The main objective of root canal therapy is thorough shaping and cleaning of all pulp spaces and its complete obturation with an inert filling material. The presence of an untreated canal may be a reason for failure. A canal may be left untreated because the dentist fails to recognize its presence. It is extremely important that clinicians use all the armamentaria at their disposal to locate and treat the entire root canal system. It is humbling to be aware of the complexity of the spaces we are expected to access, shape, clean and fill. We can take comfort in knowing that even under the most
