

# Mechanical Ventilation in Acute Respiratory Distress Syndrome

## 6

Farhad N. Kapadia and Umakant Bhutada

A 25-year-old female patient presented with fever with chills and vomiting. The following day, she noted increased difficulty in breathing. Extensive bilateral infiltrates were seen on the chest X-ray, and she needed supplemental oxygen to maintain oxygen saturation at more than 90%. Echocardiography showed normal cardiac function. She was getting progressively fatigued and increasingly drowsy and was intubated.

Acute respiratory distress syndrome (ARDS) is characterized by a brief precipitating event followed by rapidly developing dyspnea. In addition there is a markedly impaired respiratory system compliance and reduced aerated lung volume. The hypoxemia does not correct with low concentrations of supplemental oxygen and low positive end expiratory pressure (PEEP). The mortality from ARDS is around 35–40%. Current therapy for ARDS revolves around treatment of underlying cause, using a lung protective ventilatory strategy, standard intensive care practices and appropriate multi-organ monitoring and support.

### Step 1: Initiate Resuscitation and Identify the Reason for Deterioration

- Initial resuscitation should be done, as described in Chap. 23, Vol. 2.
- Take history, perform quick physical examination, and initiate basic investigation such as arterial blood gas and the chest X-ray to arrive at a probable cause for deterioration in respiratory status.
