Abstract- Under ground-fault conditions, the flow of current will result in voltage gradients within and around the substation, not only between structures and nearby earth, but also along the ground surface. In a properly designed system, this gradient should not exceed the limits that can be tolerated by the human body. The purpose of a ground mat study is to provide for the safety and well-being of anyone that can be exposed to the potential differences that can exist in a station during a severe fault. The general requirements for industrial power system grounding are similar to those of utility systems under similar service conditions. The differences arise from the specific requirements of the manufacturing or process operations. Some of the factors that are considered in a ground-mat study are the following:

- a) Fault-current magnitude and duration
- b) Geometry of the grounding system
- c) Soil resistivity
- d) Probability of contact
- e) Human factors such as
- 1. Body resistance
- 2. Standard assumptions on physical conditions of the individual

I. INTRODUCTION

In designing and construction of an electric substation, one of the most important issues that must be considered is designing of protective system to the earth. Flows of the earth system, cause voltage gradients ground level which case different parts of the earth and the reference (ground round). The potential difference should be carefully and automatically designed. This may have enough voltage to reach the safety of people in place and causes risk. In this situation, people feel exposed to high voltages between the location of two steps (Step voltage) and also if a person at this moment in contact with the ground is a metal device, the voltage between that point and exposed earth place your foot (contact voltage).

Earth system must be designed so that the order should contact voltages and maximum values possible

step event and substation where conditions are faulty. The maximum values of contact and step voltages tolerated human body should be less.

A method for designing the earth system is based on the use of the land network in the same intervals. The results using this method largely increases system costs and the need for land will be provided in addition to better meet the safety conditions, will prevent the additional costs.

In the past, papers presented for optimizing the land in these articles, but only for optimizing the parameters are considered, the length conductors earth system. In reference [1] related to voltage changes and call the number step-conductors earth system to determine efficiency in reducing conductors increased contact and step voltages provided the tolerance values, has been compared to evaluate safety. In references [2, 3 and 4] study on compression ratio and its relationship with the conductors and the voltage step was to contact and appropriate compression ratio achieved with minimal contact voltage compared with the values of tolerance not to evaluate safety is. In reference [5] the help of genetic algorithm optimization of the network but the number conductors and earth have already been fixed and the purpose of minimizing voltage contact, but not compared with the values of tolerance. In reference [6] for optimizing the relationship between the earths system during consecutive meshes is considered. But the only optimization variable, the total length of network Conductors earth.

In references [7-9] genetic algorithm optimization performed by the reference [8]. The vertical rods considered but the authorities only as total length conductors earth system optimization point is variable. Considering the above observation is that all articles provided for optimizing the system, earth, only during the earth system as a whole. Conductors variable optimization is considered if the studies done, other parameters of the immune system of the earth effective.

AC Substation Grounding Design Mamadou Keita, Arnel Q. Molina, California State University, Sacramento, 2013 This paper presents AC substations grounding system for either conventional or gas insulated. The design of grounding systems of substations has the primary purpose of ensuring the safety and well being of personnel who may become electrically coupled to the grounding mats during unbalanced fault conditions El Dessouky El Aziz Khamis 1998 Phan 1990 In general an unbalanced fault will cause a ground potential rise of the system neutral and any conductive medium electrically connected to the neutral. The approach of this design is based on the IEEE Standard 80 2000 which discusses the following subjects safety in grounding, tolerable body current limit, primary and auxiliary ground electrodes, grounding enclosure, sizing of conductors and materials, soil characteristics, ground resistance, types of ground faults, installation of connections, pigtailed ground rods and ground grid integrity test. In this project general system structure as well as rules and data representations are discussed. An illustrative example is presented using 15 kv medium voltage switchgear for Tri Met Portland Westside light rail Thomas Pham 1999 The ac substations grounding system design presented in this project can assist grounding system engineer to obtain a safe grounding system which is one of most important design aspects of substations

Mohamed,Osama El-Sayed Gouda,2014-11-14 As the number and complexity of AC substation increase the need for accurate design procedures for the grounding systems becomes more important both from safety point of view and from financial considerations The boring test samples and other geological investigations often provide useful information on the presence of various layers and the nature of soil material as its resistivity and the range of values at the site THIS BOOK discuss New theoretical developed methods for calculation the earthing resistance and earth surface potentials of variant electric substation earthing systems i e starting from a grid consists of one mesh or rod to a final design consisting of many regular meshes or rods respectively An experimental work is carried out on an improved scale model to study the behavior of earthing systems in non uniform soil structure [Design Analysis and Optimization of Ground Grid Mesh of Extra High Voltage Substation](#) Akash Patel,2016 The 750kv substation is chosen for given a particular type of soil to design square ground grid mesh By using the line to ground fault current generated on 750kv substation by ETAP short circuit analysis ground grid parameters are determined using simple hand calculations and results are verified by modeling the same ground grid using ETAP ground grid system After getting a general idea about the effect on system generated fault on GGS System data including fault current from existing 50kv Rawat substation is gathered to verify all the crucial parameters are within the defined limit or not To evaluate important GGS parameters using ETAP 12 GGS Module mesh analysis is undertaken by both the methods which are IEEE 80 2000 and FEM The shortcoming in the already existing mesh are showed by ETAP warning followed by an alert dialog box and remedial actions are suggested to solve these problems The increase in fault current by the xi expansion of substation is considered with possible solution and calibration of ground grid mesh is presented based on modern technology Finally the comparison between IEEE 80 2000 and FEM is done in order to design GGS and effect of ground grid area a number of conductors rods and spacing between conductors are explained by help of several case study results **Calculation of Important Design Parameters for Grounding Systems in Substations**

Arun Balakrishnan,1990 **Design of an AC Substation Grounding System** Farakh Nasim,California State University, Sacramento,2007 [Substation Grounding](#) Inna Baleva,California State University, Sacramento,2012 Designing a proper substation grounding system is quite complicating Many parameters affect its design In order for a grounding design to be safe it needs to provide a way to carry the electric currents into the ground under both normal and faulted conditions Also it must provide assurance that a person in the vicinity would not be endangered The grounding portion of substation design will be explored In order to properly plan and design the grounding grid calculations of the following will be done maximum fault current grid resistance grid current safe touch and step voltages ground potential rise as well as expected touch and

step voltage levels Background information and guidelines to design a substation grounding grid will be provided A set of equations will be presented to calculate whether the design is safe and finally an example will be provided that can be used as a template Sources of Data IEEE Std 80 2000 A safe substation ground grid was designed *Analysis techniques for power-substation grounding systems : volume 1, design methodology and tests* E. B. Joy, *Grounding Grid Design for High Voltage Substations* Farhan bin Hanaffi,2016 An electrical grounding system is an important element to ascertain a safe environment for both humans and equipment during fault or transient conditions The performance of grounding systems under lightning current is quite different from the conventional frequency based power In order to understand the grounding grid behaviour under lightning current researchers typically carry out experiments on actual grounding systems or on laboratory scaled models Although experiments can provide insights of the actual grounding operation the shortcoming is that a large area of lab space is required which reflects into high costs As an alternative computer simulation has been introduced and can be categorised into three different approaches namely circuit approach transmission line approach or electromagnetic approach In this work the simulations are performed based on the electromagnetic approach under three dimensions 3D mode due to its accurate results For further understanding a comparison between circuit and electromagnetic approaches is also carried out where the resulting outcome shows that the circuit approach underestimates the impulse impedance at injection point compared with simulations by the electromagnetic approach When the electromagnetic approach is applied a finite element method is used to solve the partial differential electromagnetic equations in the time domain Thereafter the simulations results are validated with the existing published results covering the electromagnetic simulations by using the method of moment MOM and as well as actual field experiments In addition simulations are performed to understand the effect of different parameters including lightning current soil parameters grounding design and location of injection point of lightning current Moreover a comparison study is carried out for potential rise between power frequency and impulse current at different grid sizes The study shows the potential generated at injection point for both current and saturation point when the grid size reaches a certain point It's important to consider both types of current to get better grounding grid design Besides that empirical equations are used out to calculate the effective area under lightning conditions where the effect of the down conductor is taken into consideration as part of the grounding model The effective area is an important parameter for the optimization of the grounding grid design when increasing grounding size does not improve the impulse impedance Transient ground potential rise TGPR above the ground is another interesting parameter to analyse In this work a good correlation is shown between the effective area and the impulse impedance at the injection point with rising transient ground potential It is found that the TGPR is larger when it is closer to the injection point but only lasts for a few microseconds Step voltage evaluations are performed for different standing positions of the human above the grid including the distance of the step voltage location from the injection point and the effect of grid size to step voltage value
